Our Company

As a global corporation with more than 500 employees, GRW is headquartered in Rimpar, near Würzburg, with assembly facilities in Prachatice (Czech Republic) and a direct sales office in the USA

GRW is the premier developer and manufacturer of miniature precision ball bearings, assemblies and accessory parts utilizing state-of-the-art equipment and manufacturing processes. We specialize in production of high precision, small, miniature and instrument bearings as well as spindle bearings and bearing units. GRW also welcomes the opportunity to design, develop and produce customized applications using customer specifications.

Our radial ball bearings range in bores from 1 mm to 35 mm with outer diameters from 3 mm to 47 mm meeting any condition from mini series to high volume standard applications.

GRW bearings are produced in both metric and inch dimensions making them truly applicable to any customer in the world. Whether your application reguires mini series, standard high volume or customized specifications, you can always rely upon GRW to meet any requirement or challenge.

GRW complies with the highly recognized standard of quality in process and performance as evident by our ISO certification, DIN EN 9100:2018.

Headquarter and production site at Rimpar

GRW... the premier provider for customized high-precision ball bearing solutions.

Preface

"Miniature precision meets extreme demands"

In order to successfully meet the challenges of the market, our products are being continuously developed and their performance improved, based on the latest innovations from GRW.

Developments that we have achieved in the areas of product design, ball bearing steels, retainer design and materials, lubricants and surface coatings, are the basis for the technological leadership the company has today.

Our latest advance: XTRA - Enhancing Performance!

With GRW XTRA, we are not so much reinventing the ball bearing but using our expertise to improve, for example, performance levels in terms of running noise, service lifetime and speed! The ball bearing designed by GRW to your individual requirements acquires superior performance due to XTRA.

See page 79 of this product catalog for more details.

Materials for rings and balls

GRW ball bearings are manufactured by using technological advancements in steel production and heat treatment. Our ball bearings are made of chrome steel (100Cr6), stainless steel (X65Cr13), or high corrosion-resistant steel (X30CrMoN 15-1). It is now possible to achieve comparable load ratings for all these steel types.

Ceramic balls, e.g. hybrid ball bearings, can be used in all versions as required by your application.

Hybrid ball bearings

GRW hybrid, or ceramic ball bearings are made of one of the steels previously mentioned as well as silicon nitride (Si_3N_4) or zirconium oxide (ZrO_2) , both which offer specific benefits.

These types of bearings are used most commonly in dental handpieces, spindle bearings and vacuum pumps to extend speed limits or increase bearing stiffness.

Using GRW Si₃N₄ ceramic balls reduces load rating by 30 %, while the dynamic load rating remains unaffected.

The low affinity to other materials allows a particularly low adhesive wear. As a result, hybrid or ceramic bearings provide extended lifetime run times when used in mixed-torque applications.

Closures

Integrated ball bearing shields and seals provide two vital purposes: to prevent dirt and foreign particles from infiltration and to prevent lubricants from leaking out.

Non-contact shields

Together with the shoulder of the inner ring, the closure creates a narrow gap. Similar to open ball bearings, this closure neither increases running friction nor limits the maximum permissible speed because the shields do not touch the inner ring. This is sufficient for most applications. Shields prevent contamination with dirt particles but cannot achieve a hermetic seal

Metal shields Z

For the majority of our bearings, shields are stamped from corrosion-resistant steel. They are fastened and secured to the outer ring by means of a circlip and can thus be removed. Bearings can also be fitted with pressed-in shields made from a deep drawn steel sheet; these shields cannot be removed.

RZ/VZ rubber seal

The RZ closure is made of synthetic buna N rubber with a steel support shield and can be used at temperatures from -30 $^{\circ}$ C to +120 $^{\circ}$ C.

The VZ closure is made of synthetic Viton fluoroelastomer with steel support shield and can be used at temperatures from -20 $^{\circ}$ C to +230 $^{\circ}$ C.

Both shield types are secured by snap fit.

Contact seals

This type of seal touches the shoulder of the inner ring, causing an increase in start up and running torque.

Teflon[®] seals can be used at working temperatures of -240 °C to +300 °C. The friction is lower than for rubber seals due to the low friction combination (PTFE /steel) and the low contact force of the sealing lip.

Teflon® seal TS

The TS seal is made of a glass-fiber reinforced Teflon® sheet that is fastened in the outer ring by means of a circlip.

TS seals are universally resistant to chemicals. Bearings using TS seals are normally made of corrosion-resistant steel. In appropriately large quantities, TS seals can also be made available for chrome steel bearings.

RS/VS seals

The RS seal is made of synthetic buna N rubber with a steel support shield and can be used at temperatures from -30 $^{\circ}$ C to +120 $^{\circ}$ C.

The VS seal is made of synthetic Viton fluoroelastomer with a steel support shield and can be used at temperatures from -20 $^{\circ}$ C to +230 $^{\circ}$ C.

Both shield types are secured by snap fit.

Custom shields and seals

GRW can also manufacture custom accessories and combinations of different shields and seals to meet your specifications.

For improved sealing effect between steel shields and outer ring GRW offers a special laminated shield.

In this context, we would like to point out that certain lubricants cannot be used with all closures. Please consult our sales engineers about difficult applications.

Retainers for miniature ball bearings

Retainers are vital for efficient operation of ball bearings. First, they keep the balls separated and evenly spaced, ensuring a uniform distribution of load and thereby reducing heat while enhancing the bearing life expectancy.

Secondly, the retainer guides the balls in the loadfree zone and prevents the balls from dropping out of separable bearings. Using our customized designs and materials, retainers can be manufactured to meet any application. We recommend usage of a two-part ribbon retainer for the majority of applications.

In this context, we would like to point out that certain lubricants cannot be used with all retainers.

See the following list for our range of different retainer variants:

| GRW retainer designation | Illustration | Description/ material | Scope of application / purpose | | | | | |
|--------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|
| E | | Two-piece retainer made from – steel sheet (E) – stainless steel sheet (J) Retainer clamping types: – without additional sign = standard – F = retainer tightly clamped – L = retainer loosely clamped | E/J: Standard retainer for deep groove radial bearings. For stainless bearings: retainer always made from stainless steel sheet. To avoid torque peaks as far as possible, this retainer can also be mounted in a loosely clamped condition. JH: For deep groove radial bearings. | | | | | |
| JH | | One-piece snap-type retainer made of stainless steel (JH) | Used primarily for small ball bearings and low to medium speeds. | | | | | |
| TNH | 0 | One-piece molded synthetic snap retainer. | For deep groove radial bearings in medium speed range with good running and torque characteristics. Working temperature from -30°C to +80 °C, short term up to +100 °C. | | | | | |
| TNXH | O | One-piece molded synthetic snap retainer made from glass fiber reinforced plastic. X stands for a number and defines the material. | For deep groove radial bearings in a speed range above that of the TNH retainer. Working temperature from -30°C to +120°C, short term up to +180°C. | | | | | |
| THA THB | E | Machined one-piece snap retainer made from fiber-reinforced phenolic resin. A = outer ring guided B = inner ring guided | For deep groove radial bearings with very high speeds. High rigidity and emergency running properties. Working temperature from -50°C to +130°C. Can be impregnated with oil. | | | | | |
| TXHA TXHB XTRAIon | | Machined one-piece snap retainer made from a special material. X stands for a number and defines the material. A = outer ring guided B = inner ring guided | For deep groove radial bearing with very high speeds. High rigidity and emergency running properties. Working temperature, depending on the material, up to +250°C or even +300°C. | | | | | |
| | | | e retainer can also be ordered with our new retainer material XTRAIon , for even longer ce life! Please find more information about XTRAIon on page 82. | | | | | |

| GRW retainer designation | Illustration | Description/ material | Scope of application / purpose | | | | | | |
|--------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|--|
| L2T | | L2T =inner ring separable, outer ring guided | For separable angular contact ball bearings/spindle bearings with highest speeds. High rigidity. Working temperature from -50 °C to +130 °C. Can be impregnated with oil. | | | | | | |
| L2TX XTRAIon | | L2TX = inner ring separable, outer ring guided X stands for a number and defi nes the material. | For separable angular contact ball bearings/ spindle bearings with highest speeds. High rigidity and emergency running properties. Working temperature, depending on the material, up to +250 °C or even +300 °C. | | | | | | |
| | | These retainer can also be ordered with our new retainer material XTRAIon , for even longer service life! Please find more information about XTRAIon on page 82. | | | | | | | |
| TA/TB | | Machined one-piece solid retainer made from fiber-reinforced phenolic resin. A = outer ring guided B = inner ring guided Only used with AC types. Non-separable. | For angular contact bearings/spindle ball bearings with highest speeds. High rigidity and emergency running properties. Working temperature from -50 °C to +130 °C. Can be impregnated with oil. | | | | | | |
| TXA/TXB XTRAIon | | Machined one-piece solid retainer made from a special material. X stands for a number and defines the material. A = outer ring guided B = inner ring guided Only used with AC types. Non-separable. | For angular contact bearings/spindle ball bearings with highest speeds. High rigidity and emergency running properties. Working temperature, depending on the material, up to +250 °C or even +300 °C. | | | | | | |
| | | These retainer can also be ordered with our service life! Please find more information about | new retainer material XTRAIon , for even longer out XTRAIon on page 82. | | | | | | |
| VAC1 VAC2 | | Full complement bearing, without retainer, cannot be disassembled. VAC 1 = shoulder relieved on outer ring VAC2 = shoulder relieved on inner ring Outer ring or inner ring shoulder ground on one side. | Used for medium speeds, high radial loads and high axial loads in one direction. | | | | | | |
| VF | | Full complement ball bearing, without retainer, non-separable, with filling slot for inserting the balls. | Used for medium speeds and high radial loads. | | | | | | |

As not every retainer is available for all sizes, please contact us for additional information. We will gladly recommend other bearing and retainer designs as well as retainer materials for special requirements.

GRW offers some of the highest performance synthetic materials including **Vespel**®, **Torlon**®, **PEEK**, **PTFE** and **Meldin**® as well as various metallic materials and phenolic resins.

In addition to using proven materials, GRW, in close cooperation with its customers and suppliers, is constantly developing new options or enhancing existing variations. As a result, GRW is the sole owner of some exclusive licenses and patents for using specifically developed retainer materials such as the new developed premium material **XTRAION**. Detailed information concerning **XTRAION** you can find on page 82.

Lubricants

Why do bearings need lubricants?

Miniature ball bearings are perfect for high stress environments, but require special lubricants to minimize wear, in order to increase operational life, performance, and safety of the product.

GRW lubricants provide permanent lubrication to minimize sliding friction between balls, rings and retainer. This prevents excessive wear and thermal overheating, protecting balls and raceway from micro-welding and thereby extending operational life while reducing running noise. The bearing application specification determines the best type of lubrication to use.

Grease Inbrigation

Thanks to their ability to dispense a lubricating film over time, grease lubricants offer an additional advantage when being used in maintenance-free applications.

Most of GRW bearings are grease-lubricated, with approximately 300 different greases to select from. The standard recommended amount of grease (lubricant quantity) is one-third (33%) of the remaining free space in the bearing. Grease quantities deviating from this standard are indicated in the bearing part number just before the type of lubricant, preferably in percent or alternatively in milligrams.

Furthermore, our customers can choose other special treatments for grease applications, for example a

dispersion or a thin defined layer of grease. Here the designation system differentiates between TF (thin film), MF (medium film) and SF (strong film).

Oil lubrication

Miniature bearings lubricated with oil may offer advantages over those lubricated with grease.

Oil is primarily used in applications where a minimal torque is required. In particular, high speed spindle bearings are typically lubricated with high performance oils.

When compared to grease lubrication, oil lubrication sometimes uses a dispersion of oil and a solvent to achieve a better distribution of oil throughout the bearing.

With more than 100 special oils to choose from, GRW can help you to select the oil that perfectly matches your application. If no special lubrication is needed, all of our bearings whether open or shielded, are preserved with light instrument oil when they leave our factory.

Proper lubrication practices

At GRW, all bearings are lubricated during final assembly under clean-room conditions. Since dust particles can cling to the oiled or greased bearings, it is important that the customer maintains a high standard of cleanliness in their application. In addition we recommend using a clean-room for removal of the bearings from their package and during assembly.

With greased bearings, the specified quantity of lubricant, accurate to milligrams, is injected directly into specified locations of the miniature ball bearing. Usually the lubricant is injected from only one side, however it is also possible to lubricate each bearing from both sides for better distribution.

For lubrication with standard oils, the oil is poured over the bearing which is then spun. Alternatively, a specified oil quantity can be directly injected into the bearing.

Solid lubricants

Non-lubricated bearings may be used in certain applications and are also available from GRW. These non-lubricated bearings are typically required for ultra-high vacuum (UHV) temperature extremes and for applications in aviation and aerospace. Here the operating conditions go beyond the functional limits of oil and grease lubricants. The use of a bearing without a protective lubricant will negatively impact its tribological system; however lubrication with solids is a viable alternative.

GRW offers its customers a variety of different dry film coatings. Applying thin layers of precious, Wolfratherm $^{\mathbb{R}}$ or MoS_2 provides protection and lubrication for the bearing.

For oil or grease lubricated bearings, this process ensures reliable performance in case of lubricant deprivation (emergency running conditions). In GRW's part numbering system, the surface treatment of bearing components is indicated by a "B", followed by a four-digit number code indicating the type of surface treatment.

Custom treatments

In addition to varying lubricants and surface treatments, GRW can custom treat bearing components to improve tribological behavior. For example, the phenolic retainer can be vacuum-impregnated with oil (up to 5% by weight). The benefit of a vacuum-impregnated retainer is its ability to release small amounts of lubricant continually during operation. This process improves the general lubrication performance and ensures emergency running properties in lube deprived situations.

Lubricants in medical applications

Sterilization (autoclaving) is mandatory for the proper use and maintenance of medical instruments according to the guidelines of the Robert-Koch Institute. This applies to the hygienic treatment of surgical devices and dental turbines that depend on miniature ball bearings.

GRW's stainless steel and retainer materials can easily withstand sterilization in an autoclave subjected to superheated steam, where most lubricants do not survive. Combined with the extreme high speed stresses of dental turbines, these lubricants are required to provide exceptional surface adhesion and sterilization resistance.

As manufactured, GRVV bearings utilize a range of lubricants that are resistant to the sterilization process and well suited for dental and surgical devices. This optimization results in a longer life under extreme environmental conditions.

XTRAlube

For enhanced performance and longer life time we recommend the new by GRW developed lubrication **XTRAlube**.

More information about **XTRAlube** you can find on page 81.

GRW HIGH DECISION BAIL BEADING

Shaft and housing shoulders

Certain design and assembly factors are critical for optimum performance of bearings. For instance, shaft and housing shoulders should accurately allow axial load to be transferred to the inner and outer ring without permitting the rings to tilt in opposite directions.

The associated dimension tables provide limits for the largest ($d_{a \text{ max}}$) and the smallest ($d_{a \text{ min}}$) permissible shoulder diameter for the inner ring and the largest permissible shoulder diameter for the outer ring ($D_{a \text{ max}}$).

See Dimension Tables on pages 30 to 57.

Wrong, Shaft radius greater r. min

Wrong, Shaft shoulder greater than damax

Wrong, Shaft shoulder smaller than damin

Note: Similar examples apply to bearing housings.

Please note the following considerations:

- The housing shoulder diameter for the outer ring must always be smaller than (D_{a max}) and the shaft shoulder diameter at the inner ring must not be smaller than (d_{a min}).
- The corner radius between fit and shoulder must not be larger than the corner clearance (r_{s min}) of the bearing. Here an undercut is preferable to a corner radius. The edge radii of the bearing are not designed as a locating surface for the bearing in any way.
- The axial runout of the mating surfaces should not be greater than the maximum axial runout of the bearing used. Otherwise the function of the bearing will be compromised.

Correct, Shaft radius smaller than $r_{s,min}$

Correct, Shaft shoulder equal with inner ring shoulder

Correct, Support ring in place

Special installation configurations

Flanged bearings

Using miniature and instrument bearings with a flange on the outer ring offers several advantages.

Stepped housing bores, which make it impossible or very difficult to maintain accurate alignment of both bearing fits, are no longer necessary. There is also no need for the use of circlips, which create difficulties in small housing bores or thin-walled housings.

Flanged bearings assembled in narrow housings, such as gearboxes, are particularly effective.

This allows for the accurate axial positioning of the Duplex bearing pair.

Bearings with extended inner rings

Bearings with an extended inner ring simplify design and mounting of various assemblies. Shims, washers and other spacers are not necessary. Stepped shafts are also redundant.

Bearings with reinforced outer ring

Ball bearings whose outer rings are supported by the proper housing fit can withstand the highest loads. To increase the load capacity of a bearing which is not pressed into a housing, it takes advantage of a reinforced outer ring. These types of bearings can be used as "rollers".

Proper installation, general

Assembly in narrow housings

Application of a Duplex bearing

Bearings with extended inner ring

Bearings with reinforced outer ring

Fitting tolerances

Among other factors, the fit of the bearing on the shaft and in the housing significantly affects the operational behavior of miniature ball bearings. When selecting fitting tolerances the following criteria should be considered:

Rotation conditions

Rings with circumferential loading should have a tighter fit than rings with a single point load. Circumferential loading occurs when the ring is rotating and the load is static, or when the ring is static and the load is rotating.

Point loading occurs when the rings and loads are both static, or when the rings and loads are both rotating in the same direction with equal speed. Please refer to the table "Shaft tolerances" and "Housing tolerances".

Running accuracy

The same high standards of accuracy and surface quality applicable to the bearings must be applied to the shaft and housing bore.

Loading

Higher loads require a tighter fit between ball bearing, shaft and housing.

Temperature

There may be temperature differences between the bearing and mating components while the bearing is in operation. Dimensional changes caused by differential thermal expansion should be considered when selecting a bearing.

With miniature bearings it is very important to select the proper fit for the highest accuracy and reliability, hence only a close sliding or transition fit is generally required. In addition irregularities on the shaft or in the housing bore are transferred to the relatively thin-walled bearing rings.

In order to improve the fit, it is possible to classify and sort the bore and outside diameters into groups (also refer to the chapter "Calibration of bore and outside diameters"). The values shown in these tables "Shaft tolerances" and "Housing tolerances" are only valid for materials with the same expansion coefficient (11 x 10^{-6} 1/K). For different expansion coefficients, or when there are temperature differences between the bearing rings and the shaft or housing, a tolerance should be selected which ensures the appropriate fit at operating temperature.

Note: For certain environmental conditions, an adhesive may be used to secure the bearing rings. Please contact our sales engineers for additional information.

Recommended fittings

The recommended fits listed below assume mean tolerances obtained from empirical performance data.

Shaft tolerances

| Bearing bore Quality → Tolerance in µm Tolerance in .0001 inch → | PO 0/-8 0/-3 | P5 0/-5 0/-2 | 0/-2.5 0/-1 | ding -2.5/-5 -1/-2 | Type of fit |

Note:

The information on this page applies to steel shafts and housings. If applicable, linear expansion coefficients of other materials (e.g. aluminum housings) must be taken into consideration for other operating temperatures.

For more information on grading, refer to the chapter "Calibration of bore and outside diameters".

Load ratings and L-10 life

The static radial load rating Cor

The basic static radial load rating ($C_{\rm Or}$) applies to bearings which rotate at very slow speeds, which are subjected to slow oscillations or are stationary under load. Per DIN ISO 76, the basic static radial load rating is the static radial load corresponding to a calculated contact stress of 4200 N/mm² at the center of the contact ellipse of the most heavily loaded ball or raceway. If the contact pressure exceeds this maximum permissible value, plastic deformation will occur affecting the efficient operation and the life of the bearing. In other words, the basic static radial load rating is the maximum allowable radial load for the bearing. The basic static radial load rating for hybrid bearings with ${\rm Si}_3{\rm N}_4$ balls will be approximately 30 % lower than for steel ball bearings.

Static bearing capacity

Static loads including radial and axial components must be converted into the static equivalent radial load (P_r) to assess the static bearing load capacity. (P_r) is the static radial load which causes the same contact stress at the center of the contact ellipse of the most heavily loaded ball or raceway which occurs under actual load conditions. It is defined as follows:

$$P_r = X \cdot F_r + Y \cdot F_\alpha$$

P, : Static equivalent radial load [N]

X : 0,6 Y : 0,5

 F_r : Largest radial load occurring [N] F_a : Largest axial load occurring [N]

Where: $P_r = F_r$ if $P_r < F_r$

Basic dynamic radial load rating C_r

According to DIN ISO 281, the basic dynamic load rating (C₁) for radial ball bearings is the constant radial load at which a sufficiently large group of apparently identical bearings can endure one million revolutions before showing evidence of material fatigue.

Fatigue load limit C_u

The fatigue load limit ($C_{\scriptscriptstyle U}$) is defined as the radial load under which no material fatigue will occur. For ball

bearings manufactured with commonly used high-quality materials, the fatigue load limit is reached at a contact stress of approximately 1500 N/mm².

The load ratings calculated in this Product Catalog have been computed using a curvature of 52-53 % according to DIN ISO 281. Depending on the bearing geometries, the actual load ratings may differ.

Nominal life L₁₀

The "nominal life" (L_{10}) of a group of apparently identical ball bearings is the life in millions of revolutions, or number of hours, that 90 percent of the group will complete or exceed before the first evidence of material fatigue occurs. For a single bearing, (L_{10}) also refers to the life associated with 90 percent reliability.

This calculation per ISO DIN 281 assumes identical operating conditions including a constant lubricating film separating the ball complement from the raceway during the entire life of the bearing.

The L-10 life of miniature ball bearings is calculated as follows:

$$L_{10} = \left(\frac{C_r}{P_r}\right)^3$$

 L_{10} : basic rating life for a reliability of 90 % [10^6 revolutions]

 C_r : basic dynamic radial load rating [N]

P, : dynamic equivalent radial load fatigue occurs.

Taking a constant speed for granted, then the number of revolutions may also be expressed as L-10 life in hours (L_{10h}) :

$$L_{10h} = \frac{10^6}{60 \cdot n} \cdot \left(\frac{C_r}{P_r}\right)^3$$

with

L_{10h}: basic rating life L10 [h]
n : speed of the inner ring [min⁻¹]
C_r: basic dynamic radial load rating [N]
P_r: dynamic equivalent radial load [N]

Extended modified rating life L_{nm}

In addition to the nominal life rating (L_{10}), DIN ISO 281 introduced an extended modified life rating (L_{nm}), and adds a life coefficient (a_1) and operating conditions ($a_{\rm ISO}$). In application, life rating may be considerably higher or lower than the nominal L-10 life (L_{10}). The following correlation applies:

$$L_{nm} = \alpha_1 \cdot \alpha_{ISO} \cdot L_{10}$$

 L_{nm} : extended modified rating life [10^6 revolutions]

 a₁: Rating life coefficient for a requisite reliability deviating from 90 %

a_{iso}: Rating life coefficient for consideration of operating conditions

L₁₀: basic rating life for a reliability of 90 % [10⁶ revolutions]

Rating life coefficient for Relability a₁ acc DIN ISO 281

| Reliability % | L _{nm} | α |
|---------------|--------------------|-------|
| 90 | L _{10m} | 1 |
| 95 | L _{5m} | 0.64 |
| 96 | L _{4m} | 0.55 |
| 98 | L _{3m} | 0.47 |
| 98 | L _{2m} | 0.37 |
| | | |
| 99 | L _{lm} | 0.25 |
| 99.2 | L _{O,8m} | 0.22 |
| 99.4 | L _{O,6m} | 0.19 |
| 99.6 | L _{O,4m} | 0.16 |
| 99.8 | L _{0,2m} | 0.12 |
| | | |
| 99.9 | L _{O,1m} | 0.093 |
| 99.92 | L _{0,08m} | 0.087 |
| 99.94 | L _{0,06m} | 0.080 |
| 99.95 | L _{0,05m} | 0.077 |

The standardized calculation method for the life rating coefficient (a₁₅₀) takes the following factors into account:

- load on the bearing
- lubrication condition
- fatigue limit of the material
- geometry of the bearing
- internal stress of the bearing
- environmental conditions

Significance of the life rating for miniature ball bearings

All standardized methods for calculating the L-10 life assume that failure is attributable to material fatigue. However, this type of failure occurs very rarely in miniature ball bearings. Rather, miniature ball bearing malfunctions are usually attributed to contamination, retainer wear or lubricant failure. Therefore, L-10 life is theoretical and merely a guide. When estimating the L-10 life of a miniature ball bearing, the exact environmental conditions of the application should be considered.

Limiting speeds

Various mechanical and kinematic factors impact the maximum operational speed of a bearing. The following factors can have an effect on the limiting speed:

- Retainer load
- Noise
- Rolling kinematics
- Lubrication
- Heat generated by friction and the environment
- Inner ring slippage and radial play reduction

Retainer loading

In miniature bearings, the speed limit can be determined among other factors by the retainer material and its design.

Practical experience has shown that machined synthetic retainers are better qualified for the highest speeds. These retainers generate smaller imbalance at high speed because of their small mass and the accuracy by which they are manufactured. They are characterized by higher density and elasticity enabling them to withstand the alternating forces generated from ball acceleration and deceleration.

With more than 40 different retainer materials, our product range offers an appropriate technical solution for nearly every application.

Heat

All bearing assemblies have a maximum operating temperature, which ultimately limits the bearing speed. This maximum temperature is not only defined by the bearing's mechanical components, but also by the temperature range of the lubricant. In general, the operating temperature achieved at a certain speed depends on the torque generated in the bearing and the assembly's ability to transfer heat to the environment.

This assumption is the basis for calculating the thermal reference speed as noted in DIN ISO 15312.

Thermal reference speed

The thermal reference speed $(n_{\theta r})$ defines the speed of the inner ring at which a balance is achieved between the heat generated in the bearing by torque and the heat flow dissipated through the shaft and housing.

For the standardized calculation method noted in DIN ISO 15312, the following conditions apply:

- Mean ambient temperature $\vartheta_{\Lambda_c} = +20$ °C
- Static temperature at the outer ring $\vartheta_{c} = +70$ °C
- Standard bearings without seals
- 5% of the static load rating as pure radial load
- Lubricant: mineral oil with a kinematic viscosity of $v_{c} = 12 \text{ mm}^2/\text{s}$ at $\vartheta_{c} = +70 \text{ °C}$

Significance of the thermal reference speed

The calculation of the thermal reference speed is general and does not take into consideration application specific conditions. As such the thermal reference speed is to be used merely as a guideline value allowing for direct comparison of the different bearing sizes.

Significantly higher speeds can be achieved with special modifications of the components surrounding the bearing and of the bearing itself. Through the use of $\mathrm{Si_3N_4}$ (ceramic) balls, a highly accurate synthetic retainer, a higher bearing tolerance grade and a high-performance lubricant, significantly higher speeds can be achieved.

Elastic behavior of deep groove radial bearings

With ball bearings, two types of deformation have to be distinguished: axial and radial elastic deformation.

Axial elastic deformation

The axial elastic deformation of a ball bearing is the distance that the inner ring moves axially relative to the outer ring when the axial clearance of the ball bearing has been removed and an increasing axial load has been applied. This value does not increase linearly with increasing axial load; rather the contact ellipses between balls and raceways become larger as the load increases

Radial elastic deformation

Similarly the radial elastic deformation is caused by a radial load component after radial clearance has been removed. Under otherwise identical conditions, with a small contact angle, the radial elastic deformation is considerably less than the axial elastic deformation. With an increasing contact angle, the radial yield increases while the axial yield decreases until both values become roughly identical at approximately 35°.

Both types of deformation depend on the internal geometries of bearing, the existing radial clearance and applied load.

Effect and application

The relatively large amount of yield can be reduced by using preloaded bearing pairs (see chapter "Duplexed bearings"). Preloading will result not only in a reduction of the elastic yield, resulting in increased stiffness, but also in a nearly linear relationship between loading and yield for a considerably wide range of applied loads.

For example: A ball bearing pair with a 10 N preload will maintain linearity up to approximately 30 N of applied axial load. Exceeding this load value will cause the balls to lose contact with the raceway transferring the load to one bearing.

The following formula provides an estimation of the axial preload:

Fv: axial preload [N]
Fa: axial bearing load [N]

With a contact angle of 15° (C), the radial stiffness of bearing pairs is assumed to be approximately six times as high as the axial stiffness. With a contact angle of 25° (E), a factor of 2 is assumed.

Specific material properties always play an important role. In hybrid bearings using ceramic balls (e.g. Si_3N_4 , ZrO_2) the material properties of the ceramic balls should be taken into consideration. Due to the lower elasticity of the ceramic material, these bearings are stiffer than bearings assembled with steel balls. The stiffness of bearings using balls made of Si_3N_4 is about 30 % higher than the stiffness of bearings using steel balls.

Specific applications must consider the operating temperature which can affect the bearing clearances. Likewise, differing thermal expansion coefficients may play a decisive role in bearing material selection.

For further information, please contact your nearest GRW Sales Representative.

Relationship between radial play, axial play, contact angle and tilting angle

Radial play

Radial play has minimal effect on the quality of a bearing; however it does have a significant effect on its performance. For example, the bearing's life rating, running noise, vibrations and thermal behavior all depend on the appropriate radial play. (See chapter: "Reduction in radial play")

Radial play is the measurement of the total movement of one ring relative to the other in a plane perpendicular to the bearing axis. In selecting the appropriate radial play, the fit of the bearing on the shaft and in the housing is of particular importance.

Larger than the standard radial play (4-11 μ m) should be selected if the ball bearing runs under axial preload and operates at high speeds, or if low torque is required.

Less than standard radial play should be specified if a radial load is applied or low noise is required.

Less than standard radial play is often specified to reduce the axial play in the application. When a very low axial is required we recommend using duplexed bearings (see the chapter "Duplexed bearings").

In deep groove bearings, there is a definite correlation between radial and axial play that is controlled by the internal geometries. For the individual radial play groupings and their respective references, refer to the section titled "Radial Play Classification".

Axial play

The axial play is the measured value in which one bearing ring can move axially in relation to the other with no applied load.

Contact angle

In a load-free condition, the contact angle is called the nominal contact angle. The contact angle is the angle between a plane perpendicular to the ball bearing axis and a line joining the two points where the ball makes contact with the inner and outer raceways. The contact angle of a ball bearing is determined by its radial play, as well as its inner and outer track curvatures.

The contact angle under load is called the operating contact angle. Deformations of a defined size occur at the contact points between balls and raceways. The deep groove radial bearing is a relatively rigid bearing with a very small contact angle range. Here, a highly accurate bearing alignment is of the utmost importance.

Tilting angle

The tilting angle of a bearing is the relative angle to which the inner and outer rings of a bearing can be tilted. The amount of tilting depends on the radial play and the internal geometries of the bearing.

Tilting of the rings should generally be avoided. Even small tilt angles of 2° or 3° may result in increased bearing noise and reduced life. It is critical to place close attention to machining tolerances of mating assembly components to assure proper bearing alignment.

Calibration of bore and outside diameters

To guarantee a uniform fit of bearings on the shaft and in the housing, it is imperative to control diameter tolerances of the bearings. It is very difficult to control very small tolerances in a production run; therefore, sorting of the rings may be necessary. Only bearings in quality grades P5 and ABEC5 or better can be sorted into groups of 2.5 μ m (.0001 inch) or 1.25 μ m (.0005 inch). The diameters of the shaft and housing must also be accurately measured and sorted to match.

For technical reasons, it is not possible to supply bearings in only one specific tolerance group. This means that grading to X4, only 3 of 4 possible groups can be contained in the shipment lot, i.e. the final group distribution is subject to production machining variances.

The following symbols are used for the classification of graded ball bearings:

Classification of graded bearings

| Grading | in groups of 2.5 µm or .0001 inch | in groups of 1.25 µm or .00005 inch | in groups of 1 µm or .00004 inch | | |
|-------------------------------|--------------------------------------------|----------------------------------------------|-------------------------------------------|--|--|
| Bore d and outside diameter D | X | X4 | X5 | | |
| Bore d only | ХВ | X4B | X5B | | |
| Outside diameter D only | XD | X4D | X5D | | |

Example:

SS624 P5 GPR X4B J L001 X4B = bore graded in 4 groups of 1.25 μ m. The outside diameter is not graded.

Key to tolerance groups

| | | | | | Outside diameter D | | | | | | | | | | | | |

| | not graded | | |) | XD | | X | 4D | | | | X5D | | | Syn | nbol | |

Different tolerance groups are defined by grading. On the package of each bearing, the relevant group is indicated by means of the following code:

Examples:

| Code 21: | Code BC: | Code A0: | Code 02: |
|----------------------------------------------|--------------------------|----------------------|-----------------------------------|
| Bore- \varnothing $-2.5/-5 \mu \mathrm{m}$ | Bore-∅ -1.25/-2.5 µm | Bore-Ø 0/−1.25 μm | Bore-Ø not graded |
| Outside-Ø $0/-2.5 \mu m$ | Outside-Ø -2.5/ -3.75 µm | Outside-Ø not graded | Outside-Ø $-2.5/-5 \mu \text{m}$ |

Method of group classification:

Bore diameter: The smallest measured diameter defines the class.

Outer diameter: The largest measured diameter defines the class.

Reduction in radial play

Ball bearing radial play can increase or decrease during operation due to external influences.

Increases in radial play can cause an increase in contact angle, which distorts the contact ellipse at the transition between raceway and shoulder. This "excessive edge loading" phenomenon may cause premature bearing failure.

In the worst case a reduction in radial play may cause excessive radial preloading of the bearing causing accelerated bearing wear and premature bearing failure.

The following factors have direct influence on changes in radial play:

- Temperature gradients within the bearing or materials with different temperature coefficients.
- Shaft and housing fits.
- Speed related Centrifugal forces.

Reduction in radial play due to thermal expansion

Bearing clearances are set at an ambient temperature of +20 °C which excludes external loads except measuring loads. Frictional heat generation or temperature differentiation between inner and outer rings can very often cause unfavorable environments. The resulting differential expansions of inner ring and outer ring change the radial play. This factor has to be considered when designing the bearing.

$$\Delta S_{RT} \approx \Delta d_a - \Delta d_i - 2\Delta Dw$$

 ΔS_{RT} : Change in radial play due to thermal expansion [µm]

 Δd_a : Change in outer raceway diameter for temperature T [µm]

 Δd_i : Change in inner raceway diameter for temperature $T[\mu m]$

 ΔDw : Change in ball diameter for temperature T [µm]

The resultant diameter change caused by the temperature difference is calculated. (Reference: ambient temperature +20 °C):

For the outer ring: $\Delta d_{\alpha} = d_{\alpha 0} \cdot \alpha \cdot \Delta T$ For the inner ring: $\Delta d_{i} = d_{i0} \cdot \alpha \cdot \Delta T$ For the balls: $\Delta Dw = Dw \cdot \alpha \cdot \Delta T$

 d_{a0} : Raceway diameter of outer ring at +20 °C [mm] d_{i0} : Raceway diameter of inner ring at +20 °C [mm]

Dw: Ball diameter at +20 °C [mm]

 $\alpha \quad : \mbox{Linear expansion coefficient } [K^{-1}] \mbox{ for }$

100Cr6 ... 11 · 10⁻⁶ X65Cr13 ... 10.5 · 10⁻⁶ X30CrMoN15-1 ... 10.4 · 10⁻⁶ Si₃N₄ ... 3.0 · 10⁻⁶ ZrO₂ ... 10.5 · 10⁻⁶

 ΔT : Temperature difference between temperature T and ambient temperature of +20 °C in [K]

Reduction in radial play due to an interference fit

Interference fits cause a reduction in radial play and so the fitting tolerance should be chosen carefully. The reduction in radial play depends on the effective interference fit and the ring thickness ratio. These ratios can be calculated as follows:

$$\Delta S_{R\ddot{U}} \approx k \cdot \ddot{u}$$

 $\Delta S_{R\ddot{U}}:$ Reduction in radial clearance due to interference fit [µm]

: Factor from the table, while it is presumed that the inner ring is pressed onto a complete shaft or the outer ring is pressed into a stable, non-deformable housing.

ü : Largest interference fit [μm]

If interference fits are used on the shaft and on the housing, the total reduction in radial play is determined by adding both values.

Reduction in radial play

Reduction in radial play due to centrifugal forces

At very high shaft speeds or inner ring rotation, the centrifugal forces of the rotating parts increase. The load on the outer ring and the balls also increases and the inner ring expands. The expansion of the inner ring changes the fit of the shaft and bearing and the bearing may begin to slip on the shaft. In this situation, a tighter fit must be selected.

These types of deformations depend on the bearing size, retainer, balls, materials used, and inner geometry of the bearing.

Please contact our sales engineers to find out more about the reduction in radial play due to centrifugal forces.

Example:

The ball bearing SS634-2Z GPR I(d = 4 mm, D = $16 \, \text{mm}$, Dw = $2.50 \, \text{mm}$, material of rings and balls: X65Cr13) is to run in an application at 35,000 1/min. During the operating phase, the temperature at the inner ring is +60 °C and at the outer ring +30 °C. The ball bearing is mounted on the shaft with a press fit j5 (+3/-2) and in the housing with a tight fit K5 (+2/-6).

Change in radial clearance due to thermal expansion:

Outer ring:

$$d_{a0} \approx (d+D)/2 + Dw = (4+16) \text{ mm}/2 + 2.50 \text{ mm} = 12.50 \text{ mm}$$

 $\Delta d_a \approx d_{a0} \cdot \alpha \cdot \Delta T = 12.500 \text{ m} \cdot 10.5 \cdot 10^{-6}$
 $1/K \cdot 10 \text{ K} = 1.31 \text{ µm}$

Inner ring:

$$d_{i0} \approx (d+D)/2 - Dw = (4+16) \text{ mm}/2 - 2.50 \text{ mm} = 7.50 \text{ mm}$$

$$\Delta d_i \approx d_{i0} \cdot \alpha \cdot \Delta T = 7.50 \text{ mm} \cdot 10.5 \cdot 10^{-6} \text{ 1/K}$$

 $\cdot 40 \text{ K} = 3.15 \text{ } \mu\text{m}$

Ball:

$$Dw = 2.50 \, \text{mm}$$

Change in radial clearance due to thermal expansion:

$$\Delta S_{RT} \approx \Delta d_a - d_{i0} - 2\Delta Dw$$

 $\Delta S_{RT} \approx (1.31 - 3.15 - 2 \cdot 0.66) \, \mu m = -3.16 \, \mu m$

The radial clearance is reduced due to the temperature difference between inner ring and outer ring by 3.16 µm.

Change in radial clearance due to interference fi t:

Outer ring:

Outside diameter: $0/-8 \, \mu m$ Housing diameter: $+2/-6 \, \mu m$ $\rightarrow \ddot{U} = 6 \mu m$

 $\Delta S_{R\ddot{U}_{G}} \approx k \cdot \ddot{U}$

 $\Delta S_{R\ddot{U}_{Q}} \approx 0.8 \cdot 6 \, \mu \text{m} = 4.8 \, \mu \text{m}$

Inner ring:

Bore: 0/-8 µm Shaft: $+3/-2 \mu m$ $\rightarrow \ddot{U} = 11 \, \mu \text{m}$ $\Delta S_{pij} \approx k \cdot \ddot{u}$ $\Delta S_{\text{Pil}} \approx 0.5 \cdot 11 \, \mu\text{m} = 5.5 \, \mu\text{m}$

The raidal clearance changes due to the interference fit by $4.8 \, \mu m + 5.5 \, \mu m = 10.3 \, \mu m$

Total change of radial clearance due to thermal expansion and interference fit:

$$\Delta S_R = \Delta S_{RT} + \Delta S_{R\ddot{U}} [\mu m]$$

$$\Delta S_P = 3.16 \mu m + 10.3 \mu m = 13.46 \mu m$$

This total reduction in radial clearance must be considered when selecting the radial clearance of the bearing.

Functional tests

There are different functional tests that can be performed by GRW. As a standard, 100% of our ball bearings are noise tested. Besides this standard testing, the following tests are available: axial vibration tests, torque test and preload measurement.

These tests ensure the uniformity of the production run and compliance with customer requirements. All functional tests carried out by GRW take place in a class R 10,000 cleanroom (ISO 14644-1, class 7).

The functional test method is always selected to simulate the intended use of the bearing.

Noise test GPR

In the GRW numbering system GPR designates 100% noise testing. Using highly sensitive noise testing equipment, the amplitude of the vibrations generated by the miniature bearings is measured at specified speeds and frequencies. This method detects imperfections, such as ball or raceway defects and isolates their root cause.

This noise test is carried out in a class R10,000 cleanroom in accordance with ISO 14644-1, class 7. A standard reference oil is used to eliminate the variable effects of different lubricants

Axial vibration test GPA

GPA stands for noise testing in the axial direction. Similar to the GPR test, the axial vibrations measured by the GPA vibration meter identify the shape and surface properties of raceways and balls in the bearings.

GPA testing measures vibration noise in four distinct frequency ranges as compared to two frequency ranges for the GPR test. The amount of movement or 'peak to peak displacement' value is also recorded. The cumulative total of these distinct measurements provides a direct understanding of the ball bearing's running behavior.

As with the GPR test, standard reference oil is used to eliminate the variable effects of different lubricants.

The GPA test is offered at an additional charge. If you require any further information, please contact your GRW sales representative.

Torque test

GRW uses different methods to measure starting and dynamic torque. The Asch testing device due to MIL-STD-206 provides very exact and reliable starting torque values. During this test the outer ring is driven and the inner ring is loaded relative to each bearing size. The standard axial loading of the inner ring is 75 g for ball bearings with an outer diameter of up to 10 mm. Ball bearings with a larger outer diameter (> 10 mm) are loaded with 400 g.

Since there is no universally accepted standard for torque measurement, the torques of identical bearings can only be compared if they have been measured under the same measuring conditions with the same measuring devices.

Table "maximum starting torque in μ Nm" shows reference values for the maximum starting torque. These values apply for instrument ball bearings without seals, P5 or ABEC5 or better, which are lubricated with instrument oil having a low viscosity ≤ 14 mm²/s at +40 °C. The values can be 10 to 40 times higher for ball bearings with grease lubrication.

Running or dynamic torque is the force required to keep a bearing in rotation. A special dynamic torque tester developed by GRW for this very purpose is available on request to measure the running torque at higher speeds.

Maximum starting torque in µNm

Assembly of low-torque ball bearings

Shaft and housing fits and tolerances for low-torque bearings are particularly important. Shaft and housing tolerances need to be selected so that they result in a sliding fit. Please refer to the chapters "Fitting Tolerances" and "Reduction in radial play".

Even a small misalignment of the inner or outer ring can result in an increased bearing torque. Particular attention must be given to the exact alignment between shaft and housing bore, as well as to the parallelism of the mating faces.

Extreme cleanliness of parts and assembly area is essential to produce a perfect low-torque bearing. Even the tiniest contaminations of the ball bearings can cause torque peaks, which may be many times higher than the average torque level.

Preloading test

Another testing device specifically developed by GRW measures and records the preloading of duplexed bearings (following the "broken curve" method). This type of measurement is available on request.

Tolerance and Runout Tables – inner ring

(International Organization for Standardization) and ABEC bearings according to ABEC quality standards ABEC 1 to standards (Annular Bearing Engineering Committee). For ABEC9 (ABEC9 = highest tolerance). metric size bearings, tolerances comply with ISO quality

GRW bearings conform to the applicable ISO PO to P2 (P2 = highest tolerance) and for inch size

GRW manufactures miniature ball bearings according to Including tolerances of mating parts, such as shafts and the highest quality standards for both inch and metric sizes. housings, to create a bearing friendly environment. GRW's sales engineers will be pleased to support you selecting the suitable quality for your application.

⁽⁵⁾ For spindle bearings only
⁽⁶⁾ Nominal value for bores of 9 mm and up

 $^{^{(1)}}$ Tolerance for matched bearings is 0/-200 μm

⁽²⁾ Applicable before assembly of the bearing and after removal of the inner and/ or outer circlips

⁽³⁾ For flanged bearings inboard side of the flange

⁽⁴⁾ For deep groove radial bearings only

Tolerance and Runout Tables – outer ring

⁽¹⁾ $r_{s\,min}$ = minimum single bearing chamfer or maximum permissible shaft or housing fillet radius (2) Other load ratings are possible with different ball complements and non standard retainers (3) Different shields and seals are available

⁽⁴⁾ Bearings also available with 1 or 2 shields/seals
(5) Limiting speed also depends on seal, material and the respective ball complement

[•] Bearings without shields or retainers are also available with recesses.

Please discuss your desired design in terms of flange, extended inner ring width, shield, lubrication, and material with our Technical Application Consultants to check availability.

Subject to change.

Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

⁽¹⁾ $r_{s,min}$ = minimum single bearing chamfer or maximum permissible shaft or housing fillet radius (2) Other load ratings are possible with different ball complements and non standard retainers (3) Different shields and seals are available

⁽⁴⁾ Bearings also available with 1 or 2 shields/seals

 $^{^{(5)}}$ Limiting speed also depends on seal, material and the respective ball complement $^{(6)}$ Tolerance of bore +12µm to 3µm

[•] Bearings without shields or retainers are also available with recesses.

Please discuss your desired design in terms of flange, extended inner ring width, shield, lubrication, and material with our Technical Application Consultants to check availability.

Subject to change.

Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

 $_{\rm II}$ $_{\rm r_s\,min}$ = minimum single bearing chamfer or maximum permissible shaft or housing fillet radius $_{\rm II}$ Other load ratings are possible with different ball complements and non standard retainers $_{\rm II}$ Different shields and seals are available

⁽⁴⁾ Bearings also available with 1 or 2 shields/seals
(5) Limiting speed also depends on seal, material and the respective ball complement

[•] Bearings without shields or retainers are also available with recesses.

Please discuss your desired design in terms of flange, extended inner ring width, shield, lubrication, and material with our Technical Application Consultants to check availability.

Subject to change.

Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

⁽¹⁾ $r_{s,min}$ = minimum single bearing chamfer or maximum permissible shaft or housing fillet radius (2) Other load ratings are possible with different ball complements and non standard retainers (3) Different shields and seals are available

⁽⁴⁾ Bearings also available with 1 or 2 shields/seals
(5) Limiting speed also depends on seal, material and the respective ball complement

[•] Bearings without shields or retainers are also available with recesses.

Please discuss your desired design in terms of flange, extended inner ring width, shield, lubrication, and material with our Technical Application Consultants to check availability.

Subject to change.

Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

 $_{\rm II}$ r_{s min} = minimum single bearing chamfer or maximum permissible shaft or housing fillet radius $_{\rm II}$ Other load ratings are possible with different ball complements and non standard retainers $_{\rm II}$ Different shields and seals are available

⁽⁴⁾ Bearings also available with 1 or 2 shields/seals
(5) Limiting speed also depends on seal, material and the respective ball complement

[•] Bearings without shields or retainers are also available with recesses.

Please discuss your desired design in terms of flange, extended inner ring width, shield, lubrication, and material with our Technical Application Consultants to check availability.

Subject to change.

Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

Spindle / angular contact bearings

Spindle bearings are single-row angular contact bearings with a nominal contact angle of 15° (C) or 25° (E). They can be subjected to both radial and (in one direction) axial loads. The direction of the axial load is shown by a "V" marking on the outer ring. GRW spindle ball bearings are suitable for applications requiring precision while carrying high load combined with high speed.

GRW spindle ball bearings are characterized by following properties:

- Manufactured quality of P4 (ABEC7) or better.
- Rings mostly made of corrosion-resistant SV 30 highgrade steel (other materials on request).
- Steel or ceramic balls.
- Solid retainer made from fiber-reinforced phenolic resin or special materials, for special applications, speed, etc...
- 15° (C) or 25° (E) contact angles as standard.
- Optionally, bearings can be paired with three pre-defined preload classes (L, M, S) or to a specific preload.
- Oil or grease lubrication.
- Open and shielded versions available.
- Cleanroom assembly, lubrication and packaging.

Open spindle ball bearings

- Standard configuration has large balls for optimum utilization of bearing geometries and a solid retainer for higher bearing capacities.
- The outer ring has only one partial shoulder remaining.
 This partial shoulder is necessary to prevent the bearing from separation.
- Solid outer ring guided retainer with a low profile crosssection is particularly well suited for oil injection lubrication or oil mist.

Shielded spindle bearings

- Non-contact shields do not cause any additional torque caused by the shields.
- Standard shields made of Viton (VZ) coupled with a stainless steel support shield offer excellent temperature and contamination resistance.
- A very small, closely toleranced sealing gap provides protection against dust particles.
- GRW recommends using a grease lubricant for longer life and reliability.
- Dimensionally identical to non-shielded spindle bearings but sometimes different inner geometry.
- This type of design often requires use of smaller balls that results in a lower load capacity but higher axial stiffness and speed limits (usually signified by A or B after the base type).
- Also available without shields for high-speed applications.

Handling

- GRW recommends leaving the bearing in its airtight packaging until you are ready for assembly.
- Extreme cleanliness during assembly is recommended.
- Avoid to drop or to subject the bearing to any kind of impact loading.
- Spindle bearings are designed to withstand axial loads in only one direction. This direction is identified by the "V" laser marking on the outer ring.
- Using the proper assembly tooling will prevent damage of the bearing.
- Duplex bearings labeled (DB), (DF), or (DT) are always packed in pairs and can only be used as pair in the specified configuration.
- Universally ground duplex bearings can be used in a combination of configurations, i.e. you can combine bearings from different packages or lots. These bearings may be assembled in any duplex arrangement.
- Prior to using these bearings in application GRW
 has found that a run in period at high speed helps to
 distribute the lubricant and is beneficial for the bearing.

Duplex bearings

Duplex bearings are two matched bearings that provide following performance benefits:

- Accurate bearing alignment in radial and axial directions including defined clearances and controlled stiffnesses.
- Increased system reliability.
- Higher load capacity.

Duplexing of these bearings is performed by loading each bearing with with a specified preload and accurately grinding the inner and/or outer rings until the bearing faces of both rings are flush.

Paired bearings processed this way are designed to be assembled in following configurations: back-to-back (DB), face-to-face (DF) or tandem (DT) and axially loaded to the specified or required force. Duplexed bearings are designed to provide the specified preload when the ground surfaces are accurately pressed together.

The ball bearings must be mounted according to the designation on the packaging labels or "V" markings on the outer rings.

Deep groove radial bearings:

For deep groove duplex bearings, the radial play is larger than normal to facilitate the desired contact angle, rigidity, and axial load capacity.

Unless otherwise specified, GRW duplex grinds deep groove radial bearings to a preload of 5 N and a nominal contact angle of 15°. If necessary, preload and contact angles can be adjusted to a customer's unique operating requirements.

Spindle bearings:

Preload and contact angle are generally standardized for spindle bearings. GRW's standard contact angles are 15° (C) or 25° (E), preload is specified as light (L), medium (M) or heavy (S). If necessary, preload and contact angles can be customized to each customer's individual operating requirements.

| By default, GRW uses for: | | | | | | | | | | |
|---------------------------|-----------------------------|-----------------------|--|--|--|--|--|--|--|--|
| | Deep groove radial bearings | Spindle bearings | | | | | | | | |
| Contact angle α | 15° (C) | 15° (C) or 25° (E) | | | | | | | | |
| Preload FV | 5 N | L, M, S | | | | | | | | |

However, the preload should not be specified higher than necessary as this would result in an increase of start up and running torque, which in turn would directly affect the expected life of the bearing.

To achieve, an identical fit for both bearings, Duplex bearings are sorted into two groups. The bore and outer diameters are packaged in pairs with bearings from the same group. To take full advantage of these duplexed pairs, they should also be mounted with calibrated shafts and housings (see chapter "Calibration of bore and outside diameters").

Bearing fits should be carefully selected because an interference fit on the inner or outer ring will change the preload.

Installation and configuration of duplex bearings

O (<>) arrangement: Back to back (designation -1 and DB for spindle bearings)

With this bearing configuration, the inner rings are designed to be clamped together. The contact angle load path between the outer ring raceway, the ball and the inner ring raceway diverge, which results in maximum stability and stiffness against any moment loading. Radial and axial loads can be taken in both directions.

X (><) arrangement: Face to face (designation -2 and DF for spindle bearings)

With this bearing configuration, the outer rings are designed to be clamped together. The load path converges resulting in less stability and a lower stiffness against moment loading. This design more easily compensates for any misalignment of the assembly. Radial and axial loads can likewise be taken in both directions.

without preload

l preloaded

Tandem (>>) or (<<) arrangement (designation –3 and DT for spindle bearings)

The tandem-mounted bearing design is capable of taking a significantly higher axial load, but only in one direction. With this type of bearing, preloading and control of axial play can only be achieved by preloading against another bearing pair.

General: Bearings with these pairing configurations are packed in pairs or sets and must not be mixed.

without preload

preloaded

Universal (designation -4 and U for spindle bearings)

Universally matched bearing pairs have a significant advantage compared to the duplexed designs described above. They are individually ground in such a way that they can be assembled in various pairing configurations, e.g. X, O, or tandem configuration without any loss in performance. With the same preload, these single bearings can be interchanged without any problems.

Bearing sets

When a higher stiffness is specified, multiple duplexed bearing configurations may be used together to achieve the desired results. Depending on the application, these bearing sets can be made of universally paired bearings in X, O, or tandem configurations. The table below shows some examples of potential, configurations in more detail.

| | Usual designation | Mark/ arrangement | Permissible load direction | Stiffness |
|-----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|----------------------------------|----------------------------------|-------------------------------------------------------|
| (4) (4) (4) (4) | O arrangement -1 or DB | <> | axial radial | axial radial rigidity against moving torques |
| (4) (4) | X arrangement -2 or DF | >< | axial radial | axial radial |
| (4) (4) (4) (4) | Tandem arrangement -3 or DT | << or >> | radial and one direction axially | unilaterally axial radial |
| (4) (4) (4) | Universal -4 or U | <<>> Examples: >< or <> or >> or | axial radial | depending on the configuration |
| (+) | Set of bearings assembled from universally matched bearings | ><< Examples: <>> | | depending on the configuration |

Superduplex bearings

Superduplex bearings are double-row deep groove radial bearings or angular contact bearings where either the inner or outer rings are integral and the remaining rings are separate to allow for assembly and proper pre-loading. (See also chapter "Special bearings" \rightarrow Superduplex bearings or Extraduplex bearings).

For Superduplex bearings, the following configurations apply:

- Designation -5
 (
 (
 (corresponds to designation -1)
- Designation -6
- X (><) configuration (corresponds to designation -2)
- **Designation -7**Tandem (corresponds to designation -3)

^{*} The indicated speed limits are guidelines for spring-loaded single bearings with low loads; depending on the respective application, higher or lower speed limits may apply in application.

[•] Subject to change. Additional types on request!

^{**} For use with oil lubrication, these bearings are also available without shields.

• Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

Spindle bearings

^{*} The indicated speed limits are guidelines for spring-loaded single bearings with low loads; depending on the respective application, higher or lower speed limits may apply in application.

[•] Subject to change. Additional types on request!

^{**} For use with oil lubrication, these bearings are also available without shields.

• Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

Spindle bearings

^{*} The indicated speed limits are guidelines for spring-loaded single bearings with low loads; depending on the respective application, higher or lower speed limits may apply in application.

[•] Subject to change. Additional types on request!

^{**} For use with oil lubrication, these bearings are also available without shields.

• Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

Spindle bearings

^{*} The indicated speed limits are guidelines for spring-loaded single bearings with low loads; depending on the respective application, higher or lower speed limits may apply in application.

Subject to change. Additional types on request!

^{**} For use with oil lubrication, these bearings are also available without shields.

• Almost all bearing types can also be enhanced with GRW XTRA. Detailed information you can find on page 79 and following.

Profiled rollers

Profiled rollers are double-row ball bearings; which means they are able to accept axial loads in both directions, as well as high radial loads. Usually, the contact surface is shaped like a Gothic arch; the contact surface and shaft touch each other in two locations.

On request, other contour surface designs are available (e.g. V groove, spherical outer ring, etc.).

Inner and outer rings can be made of chrome steel 100Cr6 or corrosion-resistant chrome steels X65Cr13 or X30CrMoN 15-1. Balls can be made of chrome steel 100Cr6, X65Cr13 or ceramic.

GRW profiled rollers have non-contact shields. On request, contact seals (e.g. Teflon[®], NBR) are available as an alternative. The rollers are lubricated for life and are also available with FDA-approved and/or autoclavable lubricants.

For further information please contact your nearest GRW Sales Representative.

Bearing units

Bearing units are pre-mounted assemblies, comprising of at least one ball bearing, shaft or housing, optional spacers, shims or spring washers.

GRW assembles the stacked components in bearing units primarily by using adhesives. Backlash free bearing units are produced cost effectively by precisely gluing the bearings under an axial pre-load. GRW has engineered special gluing equipment and techniques to ensure high accuracy and strength.

When using GRW bearing units, customers will profit from the following benefits:

- Cost advantages by eliminating possibility of improper customer assembly.
- Pre-mounted units are easier to handle than single bearings.
- At GRW the bearings are mounted in a clean room under optimum conditions.

• Depending on the application requirements, other functional elements may be integrated in the bearing units, for example springs and seals.

Subject to change.

Thin-section bearings

Thin-section bearings are bearings with very thin ring cross-sections (light ISO dimension series 67/68) or bearings with identical cross-sections, independent of their bore diameter (inch series: Extra Thin Series, Thin Series).

In addition to their small footprint and low weight, they are characterized by low torque and high rigidity.

Thin-section bearings are available in the following versions: open (standard), with closures, with an extended inner ring, with a flanged outer ring and as an angular contact or full-complement bearing at a maximum outside diameter of 40 mm.

The closures are available in -2Z and -2TS versions.

By default, thin-section bearings are all ABEC5. Please inquire about other available versions (e.g. Superduplex) ABEC7, and ABEC9.

Hybrid and full ceramic ball bearings

Conventional ball bearings are limited when operating at high temperatures, in a vacuum, or in a corrosive environment. All ceramic bearings have proven to be ideally suited for these extreme applications.

Zirconium oxide (ZrO_2) and silicon nitride (Si_3N_4) are typical materials used in all ceramic bearings. Both provide excellent corrosion and temperature resistance as well as other mechanical properties.

Material properties:

| Properties | Unit | Si ₃ N ₄ HY | ZrO ₂ ZO |
|------------------------------|-----------|--------------------------------------|------------------------|
| Density | g/cm³ | 3.2 | 6.05 |
| Hardness | Rc | > 75 | > 69 |
| E-module | GPa | 320 | 200 |
| Poisson coefficient | | 0.26 | 0.2 |
| Linear expansion coefficient | x10-6 K-1 | 2.9 | 10 |
| Max. temperature | °C | 800 | 600 |
| Corrosion resistance | | very good | good |
| Electrical conductivity | | insulator | insulator |

High chemical resistance

All ceramic ball bearings have specific advantages for applications with mixed-torque because they remain operative for a longer period of time than conventional steel bearings even in the case of lube deprivation.

Corrosion resistance

All ceramic bearings resist cold micro welding to other materials which allows for particularly low adhesive wear. Certain applications make use of conventional bearings almost impossible. For example: corrosive material resistance of all ceramic bearings allows for usage in chemical applications.

Thermal expansion

Full ceramic bearings will remain dimensionally stable even at high temperature fluctuations.

Non-magnetic and current insulation

The non-magnetic properties of ceramic materials prevent interference with magnetic fields and furthermore acts as an insulator preventing current flow.

Special ball bearings

GRW develops and produces a complete range of custom bearing options.

Superduplex bearings

Superduplex bearings are also known as double row deepgroove ball bearings or angular contact ball bearings featuring split inner or outer rings. One of the ring sets, either outer or inner, consist of a double row integral set of raceways.

This compact design permits easy handling and assembly. The inner or outer split rings are paired according to customer specifications ensuring that GRW bearings will meet the required axial preload.

Extraduplex bearings are double-row deep groove radial bearings or angular contact ball bearings with a split inner or outer ring. One floating ring is accurately preloaded and then laser-welded in place. This style of bearing prevents radial offset or changes in axial preload during assembly.

Tandemduplex bearings are designed with double-row deepgroove bearings. The raceways are extremely close to each other (in the micron range). These bearings are designed to handle both radial loads and axial loads in one direction by ensuring that the load is evenly distributed to all balls.

GRW can produce single or double-row bearings with a spherical faced or grooved outer ring and also can provide molded and plastic rubber type assemblies.

Integrated shaft bearings

Bearing and shaft can be combined to provide an integrated assembly. In this design the raceway is ground on the shaft and the bearing assembly is delivered completely assembled ready to use.

Bearing / housing assemblies

For these special designs, the raceway of the outer ring is ground directly into the housing. Complex housings, flanges and threaded mounting holes maintain the tight tolerances necessary for proper installation.

Precision components

GRW manufactures precision spacers and precision components that incorporate threads, steps, grooves, bores, etc. to tolerances in the micron (μ) range.

Coated bearings

Sometimes the use of conventional lubricants is impossible especially in applications where there is exposure to extremely high or low temperatures, ultra-high vacuum, or in close proximity to optical systems.

The solution in these cases may be special coatings with gold, silver, MoS_2 , or Teflon[®]. These thin layers act as a **dry film lubricant**. Development of this technology has made applications possible even at temperatures of -270 °C to +400 °C or in a high vacuum.

Protection against wear is also an advantage of using thin coated bearings. Raceways, balls, or outer surfaces can be thinly coated to meet each application's requirements. Possible uses for these types of coatings are profiled rollers, paper cutting blade wheels, bearings used in chemical or food processing industry, medical instruments, aerospace and vacuum technology.

As each coating can be applied by a variety of technologies, GRW will work with each customer to select the optimum coating process to meet your application requirements.

ENHANCING PERFORMANCE!

XTRAlube / Lubrication for longer life
XTRAlon / The Premium retainer material

XTRA Enhancing Performance!

In order to successfully meet the challenges of the market, our products are being continuously developed and their performance improved, based on the latest innovations from GRW.

Developments that we have achieved in the areas of product design, ball bearing steels, retainer design and materials, lubricants and surface coatings are the basis for the technological leadership the company has today.

With GRW XTRA, we are not so much reinventing the ball bearing but using our expertise to improve performance levels in terms of running noise, service lifetime and speed for instance. The ball bearing designed by GRW to your individual requirements acquires superior performance due to XTRA.

XTRA - the GRW solution for your challenges!

For more information about XTRA contact our sales engineers. They will be glad to advise you.

> worldwide: +49 (0) 93 65/819 - 0 TO USA: +1 (860) 769 3252

XTRAlube

For the toughest operating conditions in special applications, GRW relies on developing its own lubricants, which have the potential for significantly longer life: XTRAlube.

The new XTRAlube developed in the GRW laboratory delivers outstanding results both in the test criteria which GRW considers crucial and in the various functional tests. It also has the special ability to adhere to the contact surfaces of the inner ring and outer ring much better than standard greases.

In the specific case of ball bearings for dental turbines this property is particularly sought after, because the air extracted from the turbine flows partly through the ball bearings and transports the grease reservoir to the outside very rapidly. This leads to a situation of inadequate lubrication, which is responsible for the failure of the ball bearings.

Average value at life test on the GRW test bench Orakel III. Initially lubricated and no relube during test.

80 I

GRW HIGH-PRECISION BALL REARING

XTRAIon

Our premium material is designed for the most demanding requirements in terms of friction, thermal stability and wear. The unique production method involving the chemical binding of solid lubricant to the base polymer polyamidimide (PAI) creates a homogeneous, dense fabric, which offers little opportunity for attack by the superheated steam during autoclaving.

The fine distribution of solid lubricant and the chemical bond to the base material means that the exceptional property of dry-running suitability is obtained, even in extreme applications where idle speed of n \times dm > 1.000.000 mm/min are the norm. In internal tests on GRW's own test rigs, service lifetimes of up to 15 hours were attained with completely dry ball bearings. All conventional retainer materials fail after only a few minutes in the same test.

The SEM images show the surfaces of **XTRAIon** and PAI mod. after 1.000 cycles of sterilization by steam under pressure. It can be clearly seen that the surface structure of **XTRAIon** is preserved, while the PAI mod. has a very jagged surface.

SEM image: PAI mod.

→ Fig. 3 SEM image: XTRAlon

Performance overview of standard retainer materials compared to GRVV **XTRAIon** used in high-speed dental handpieces.

Life time test with XTRAlon modified ball bearings without initial lubrication:

Effect of the retainer material to the life time of dental turbines without any initial lubrication tested on Orakel III test bench (n=350.000 min⁻¹).

Your Success with GRW XTRA bearings:

As part of a development project for a major GRW customer, extremely high performance improvements over the current product design were obtained, in conjunction with XTRA developments. As part of this, parameters such as running noise, product service life and idle speed were tested on GRW internal test rigs and optimized by applying XTRA advancements.

GRW customers benefit from our XTRA bearings:

- Silent bearings ensure a more pleasant work in the dental field and any other application
- The high product reliability of GRW XTRA bearings ensures longer life time and reduces costs.
- Higher idle speed.
- GRW XTRA makes ball bearings resistant and more durable despite poor care, extreme temperatures and highest speeds.

Our benchmarks and results using XTRA products:

| Measurable target | 2013 | 2014 XTRA | Improvement |
|-------------------|---------|--------------|----------------|
| Noise [dB(A)] | 70 | 65 | - 29% * |
| Life time [h] | 90 | 260 | + 189% |
| Early failure [h] | > 50 | > 120 | + 140% |
| Idle speed [rpm] | 360.000 | 370.000 | + 3% |

Improvement of a high speed handpiece of a GRW customer.

 * Decrease by 10 dB is a reduction of the noise level by 50% (logarithmic scale).

Effect of retainer design on the running properties of high-speed dental ball bearings.

Accessories

Shims AS

For production engineering purposes, shims are often used to balance the accumulation of tolerances (tolerance chains) and axial tolerances.

GRW spring washers are made of corrosion-proof 1.4310 (AISI 301) spring wire. They are heat-treated, burr-free, and have an extremely fine surface finish

Spring washers WF

Spring washers are used for defined axial preloading of bearings, particularly for miniature and small ball bearings. The manufacture of these spring washers includes cutting and punching processes. Through a subsequent finishing process, they can be calibrated to provide highly accurate preload tolerances for special applications.

GRW spring washers are made of corrosion-proof 1.4310 (AISI 301) spring wire. They are heat-treated, burr-free, and have an extremely fine surface finish. Our spring washers are designed with 3 waves ensuring even support of the bearing during axial preloading.

Material 1.4310 (AISI 301). Before planning to use shims and spring washers, please check on availability. Other sizes on request. Subject to change. Minimum quantity 100 pieces.

Accessories

Retaining rings – (shaft circlips WSR, bore retaining rings BSR)

Retaining rings are precision engineered components designed to be applied on shafts or in bores providing a shoulder that accurately positions, locates and retains parts of an assembly. They are especially useful with small and evenly distributed axial and radial loads. It is important to ensure that the face of the retaining ring does not touch the edge radius of the bearing. If the face does touch the radial edge, we recommend that you use our shims in conjunction with our retaining rings.

GRW retaining rings are constructed from cold-drawn spring wire 1.4310 (AISI 301), which exhibits a constant cross section. They are corrosion-proof and free of any scale or burrs.

Test engineering

Orakel III

The test module developed by GRW can be freely lined to form test series. Automated and with a minimum of personnel expenditure, it tests the lifetime of high-speed dental handpieces, allowing for fast and efficient comparison of a development stage with the previously determined reference.

For evaluation of the performance characteristics of the entire system, the test process in respect of the mechanical load cycle and test criteria can be parameterized and is thus objectively reproducible. Calibration, test parameter settings and documentation of results are carried out on a commercially available PC. The actual test is carried out self-sufficiently.

Benefits:

- Up to 7,000 cycles can be executed without interruption.
- Uniform test process can be exactly reproduced.
- The operation of the modules only requires power and clean compressed air.
- Testing capacities can be expanded at any time by adding additional modules.
- Easy documentation: For each cycle, the measured speed is stored and can be written in a text file along with details of the completed testing time.
- Up to 10 modules can be controlled by one PC.

Note: Orakel III, the test module developed by GRW, is available for purchase. Contact us for more details.

GRW laboratory services

GRW – the specialists in high-precision miniature ball bearings now offer laboratory services as well.

Do you want to analyze materials? Do you need surface treatment but do not have your own laboratory or do you simply lack the expertise?

Then act flexibly and make use of the services of a competent analysis and chemistry laboratory!

We are the right partner, especially when it comes to such demanding procedures as FTIR spectroscopy with ATR technology or the functional and decorative gold plating of components.

GRW offers the following services:

General analysis, e.g. the determination of

- pH
- Acid concentration
- Oil or preservative content
- Evaporation residue
- Nitrite levels

Lubricant analysis with determination of protection by means of

- Dissolving and filtering
- Microscopy
- FTIR analysis

SS:

Surface treatments

- Gold plating
- Ultrasonic cleaning
- Hot and cold bronze finishing
- Passivating high-alloy steels

Medical hygiene treatments

- Steam pressure sterilization
- Thermal desinfection

Condensation – and salt spray test

 Corrosion testing according to DIN 50021 / ASTM B117-73 As a partner of laboratory network GRW is able to offer you additional services apart from our own spectrum:

Examinations with scanning electron microscope (SEM) and X-ray spectroscopy (EDX)

X-ray fluorescence analysis (RFA)

Detailed analysis by means of differential scanning calorimetry (DSC)

Thermal gravimetric analysis (TGA)

90 I

Proper handling of GRW high-precision miniature bearings

GRW ball bearings are manufactured and packaged with extreme care to avoid contamination, corrosion, and other external influences on the bearings. When mounting ball bearings, please mind:

- Bearings should be stored in their original package in clean, dry rooms under constant temperature conditions.
- Bearings should only be removed from their original package shortly before they are mounted. Usage of gloves, finger cots, and tweezers are recommended.
- Assembly location has to be clean and bright. All mating parts have to be clean. A hard surface is preferred.
- When mounting a ball bearing, the assembly force must not be applied over the balls. Suitable mounting tools must be used. Non-compliance with these instructions may easily result in damage to balls or raceways, for example ball indentations may occur in the raceway.
- If glued interfaces are used, ensure that any excess glue does not enter the bearing.
- Re-lubrication should only be carried out with a lubricant of the same type and purity.

- We recommend to have the bearings lubricated by GRW as this is executed in a clean room shortly before packaging.
- Selective sorting of all mating parts will help to guarantee the proper fit of the bearing to the shaft or housing.
- We recommend a running in process for greaselubricated bearings prior to use at low speed to achieve optimum distribution of the lubricant.
- Electrical current running through the bearing should be avoided.

Bearing Analysis

Based on over 70 years of expertise, GRW can provide ball bearing analysis to establish the root cause of failure or to estimate the remaining life of the ball bearing. For more information about bearing analysis, please contact your nearest GRW Sales Representative.

Valuable results can be achieved when bearings are disassembled and examined after a certain period of operation before failure has occurred. Marking of the bearing rings during disassembly can help to reproduce original assembly characteristics.

Shaft assembly

Ball indentation in raceway acused by particles

Packaging

Correct packaging protects bearings from contamination, corrosion and damage during transport and storage. We recommend the package to open just prior to mounting and to use bearings with opened packages as soon as possible.

Each bearing package is labeled with the exact design specification and the respective product lot number, factory batch number, and the packaging date of the bearing.

Our Standard packaging options are as follows:

Strip Packaging "CP"

Our standard packaging contains ball bearings in one strip or pill pack, sealed individually in transparent synthetic film packets with a white backing. The quantity per strip depends upon the outside diameter of the bearing.

Vacuum Packaging "LL"

Bearings are bulk packaged in a transparent synthetic film pack and sealed under vacuum. The quantity per vacuum pack depends on the size of the bearing or as specified by the customer.

Spindle bearing Packaging "CP1P"

Spindle bearings are packed in a separate envelope marked 'GRW' (CP1) and boxed individually (CP1P) to avoid damage.

Special Packaging

GRW offers a wide range of packaging options based upon our customer's requests and the requirement profile of the bearing, for example, stick packaging or aluminum envelopes.

Manufacturing in a Nut Shell

GRW high-precision ball bearings are used in a variety of industries and applications.

Before they leave our factory, they have passed several complex manufacturing steps.

Their journey starts in the turning department where our highprecision turning machines produce bearing rings from a variety of steels used by GRW.

Turning department

Customized solutions since 1942.

Customizea

After heat treat, all critical dimensions and raceway geometries are precisely machined to the micron (μ). Interim quality measurements are made in the measurement room

Grinding department

since

Honing is the last step before assembly. The finished, bearing rings run through a final process on machines co-developed by GRW for surface finishing of the raceways.

Measurement room

During the final assembly, finished components are sorted and selected to guarantee customer satisfaction and in some cases automated assembly can be used to assemble, lubricate and package bearings.

Honing department

This catalog is for general information purposes only, to point out our product portfolio. A general availability of the products shown cannot be guaranteed.

The rolling bearings contained in this catalog are basically standard products. When selecting the suitable bearing for a specific application, several influencing parameters must usually be taken into account which determine the function, reliability and economic efficiency of the bearing arrangement. This catalog contains only a simplified guide to the selection of potential rolling bearing types, but it is intended only for professional users who have the knowledge required for selection and is not intended to be a substitute for technical advice or adequate testing. If you do not have the necessary knowledge, please contact our Technical Support. It is generally the responsibility of the designer and user to ensure that all bearing specifications are met and that all necessary information is provided to the end user. This particularly affects applications where product failure and malfunction may endanger persons.

The illustrations and descriptions contained in the following are not to be understood as guaranteed product characteristics in the legal sense.

We reserve the right to make changes to the information and illustrations in this catalog. This catalog reflects the status at the time of preparation. More recent publications automatically take precedence over this catalog, provided they relate to the same subject and have been initiated by us. Therefore, please always check our electronic product catalog to see whether more up-to-date information or change notices are available for your desired product.

Although we have carefully checked and prepared all the information in this catalog, we can not guarantee freedom from errors or mistakes. We reserve the right to make corrections.

All rights reserved. Reprinting, duplication and translation - also in extracts - are only permitted with our written approval. Older catalog versions are completely replaced by this edition.
